FOREWORD

The spacecraft operational trajectory for Mission F is composed of five volumes which summarize the lunar orbital missions for a 3-month launch period, May, June, and July 1969. The contents of each volume are briefly described below.

1. Volume I - Operational Mission Profile, Launched May 17, 1969: Detailed mission description of the first launch opportunity, first injection opportunity, of the May launch window. MSC IN 69-FM-65, March 26, 1969.

2. Volume II - Operational Mission Profile Trajectory Parameters, Launched May 17, 1969: Listing of significant trajectory parameters computed at selected time points during each phase of the same typical mission described in Volume I. MSC IN 69-FM-66, March 10, 1969.

3. Volume III - Mission Summaries: May 1969 Launch Window: Summaries of CSM trajectory parameters at selected time points for each launch date in the May 1969 launch window. MSC IN 69-FM-67.

4. Volume IV - Mission Summaries: June 1969 Launch Window: Summaries of CSM trajectory parameters at selected time points for each launch date in the June 1969 window. MSC IN 69-FM-68.

5. Volume V - Mission Summaries: July 1969 Launch window: Summaries of CSM trajectory parameters at selected time points for each launch date in the July 1969 window. MSC IN 69-FM-69.

In addition to the five volumes of the operational trajectory described above, two additional documents supplement the operational trajectory:

1. Howell, E. C.; Hunt, C. R.; and Simmons, V. W.: Preliminary Lunar Orbit Attitude Sequence for Mission F. MSC IN 69-FM-51, February 21, 1969. This document contains the mission attitude timeline that shows the sequence of events for the lunar orbital phase of the mission. The event times were obtained from Volume II of the operational trajectory document and from the preliminary flight plan for Mission F.

2. Brewer, B. A.; and Vick, M. B.: TLI Ship Position and Coverage Data for Apollo Mission F Lunar Launch Opportunities for May 1969. MSC IN 69-FM-56, March 5, 1969. This document shows the injection ship positions and the launch azimuth range coverage for each day for both injection opportunities. The entry ship positions are not show.

SPACECRAFT OPERATIONAL TRAJECTORY

FOR APOLLO MISSION F

VOLUME I - OPERATIONAL MISSION PROFILE LAUNCHED MAY 17, 1969

By Lunar Mission Analysis Branch, Lunar Landing Branch,
and Orbital Mission Analysis Branch

1.0 SUMMARY

This volume is the first in a series related to the Apollo Mission F (CSM-106/LM-4) Spacecraft Operational Trajectory. This volume and Volume II present a detailed operational mission profile for a typical lunar orbital mission that would occur within a 3-month launch period: May, June, and July 1969. Mission summaries for each of the 3 months are presented in volumes III, IV, and V. For all three monthly launch windows, translunar injections are from the Pacific. The operational trajectory was designed to reflect the changes in mission ground rules and constraints since the publication of the F mission reference trajectory. The most important changes are the following.

1. The launch date is May 17, 1969.
2. The total 36° launch azimuth range is used.
3. The TLI maneuver is biased to compensate for a CSM evasive maneuver that follows LM extraction.^a
4. The time from LOI-1 to DOI is now approximately 24.4 hours rather than 22.4 hours.
5. After the nominal rendezvous, an APS burn to depletion is planned rather than a CSM rescue simulation.
6. The shorter range transearth flight times are planned.
7. The entry range is 1350 n. mi. (relative).

^aThe TLI bias and the evasive maneuver are not actually included in the translunar trajectory. The change was made after the generation of the trajectory.

The launch date for the profile is May 17, 1969; the launch azimuth is 72°; translunar injection occurs during the second orbit over the Pacific. The targeted lunar site is site 1, located at a selenographic longitude of 34.03° E and at a selenographic latitude of 2.63° N. The duration of this specific mission is approximately 7 days 23 hours; lunar orbital stay time is approximately 52 hours, and transearth flight time is 63 hours. The operational trajectory demonstrates the capability of the launch vehicle and spacecraft to meet all of the F mission objectives.

2.0 INTRODUCTION

This volume and volume II present the mission profile for the first launch opportunity (72° launch azimuth) first injection opportunity on May 17, 1969. The sequence of major events is presented in table 2-I. A timetable of mission events is presented in table 2-II. The elapsed times between all major mission events can be obtained from this chart, which is similar to the mileage charts on road maps. The May launch window summary is presented in table 2-III. The targeted lunar site is site 1, which is located 34.03° E, 2.63° N. The lunar site selenographic coordinates and elevation above the mean lunar sphere are listed in table 2-IV.

A complete trajectory description is provided in volume II, Operational Mission Profile Trajectory Parameters. The ground rules used in the design of the operational trajectory are defined in section 3 of volume I. The spacecraft (SC) weight summary and engine performance data are contained in tables 2-V and 2-VI, respectively. The assumed mission-independent expendables are presented in table 2-VII. Radar acquisition and termination data for all phases of the mission are provided in table 2-VIII. The AOS and LOS tracking information was computed for 0° and 5° minimum elevation angles for each mission phase. The tracking information and the tables and bar charts are for only the selected launch azimuth (72°) and for the first injection opportunity.

An earth orbital insertion ship and two translunar injection ships are used to provide the desired support (ref. 1). The ship locations for May 17 are as follows.

1. Insertion Ship - 25° N, 49° W
2. Injection Ship 1 - 34° S, 130° E
3. Injection Ship 2 - 14° S, 145.5° E

The insertion ship provides the required coverage for earth parking orbit insertion for the total 36° launch azimuth spread. The coverage requirement is 1 minute of postinsertion coverage above a 5° minimum elevation angle. The injection ships are placed to provide coverage for the last 2 minutes of the preignition sequence for as much of the daily window as possible. The mission shadow timeline is shown in table 2-IX(a) and 2-IX(b). The most significant points reflected by the data in table IX are that launch occurs in daylight and that earth landing occurs approximately 1 hour and 20 minutes prior to sunrise.

3.0 SYMBOLS AND NOMENCLATURE

AGS	abort guidance system
AOS	acquisition of signal
APS	ascent propulsion system
C	cross-product steering gain constant
CDH	constant delta height
CDR	commander
CMC	command module computer
CMP	command module pilot
CSI	concentric sequencing initiation
CSM	command and service modules
c.g.	center of gravity
DOI	descent orbit insertion
DPS	descent propulsion system

FTP	fixed throttle point

h_a	apogee altitude
h_p	perigee altitude
IGA	inner gimbal angle
IMU	inertial measurement unit
IVT	intervehicular transfer
Jerk	time derivative of acceleration
L/D	lift-to-drag ratio
LLM	lunar landing mission
LM	lunar module
LMP	lunar module pilot
LOI	lunar orbit insertion
LOS	loss of signal
LPO	lunar parking orbit
LOX	liquid oxygen
LV	launch vehicle
MGA	middle gimbal angle
MNBY	mean nearest Besselian year
MSFC	Marshall Space Flight Center
OGA	outer gimbal angle
OPS	oxygen purge system
PC	plane change
PDI	powered descent initiation
PGNCS	primary guidance and navigation control subsystem
PTC	passive thermal control

RDG	position target for LM powered descent guidance
RCS	reaction control system
REFSMMAT	transformation matrix from the basic reference coordinate system to the stable member (IMU) coordinate system
RT	target vector for Lambert guidance scheme
SC	spacecraft
SPS	service propulsion system
T&D	transposition and docking
TEI	transearth injection
t_{IG}	time at ignition
TLI	translunar injection
Tf	Δt from ignition time (t_{IG}) to Lambert target vector (RT)
TPF	terminal phase finalization
TPI	terminal phase initiation
VHF	very high frequency
ΔV_X ΔV_Y ΔV_Z	components of velocity to be gained in the local vertical coordinate system
X_{SM} Y_{SM} Z_{SM}	components of unit vector in vehicle stable member system

4.0 PRIMARY GUIDELINES AND CONSTRAINTS

The design of the mission and the resultant launch windows were based on the following primary guidelines and constraints.

- a. The monthly launch windows will consist of six possible launch days across a 9-day period with launches scheduled for the first, second, fourth, seventh, eighth, and ninth days.
- b. All launch dates are selected to achieve favorable lunar lighting conditions for the primary G mission landing sites.
- c. Two additional launch days are added to the normal G mission window, which consists of only the first four launch days. The additional launch days, which are targeted to site 5, accept the resultant high sun elevations at the site.
- d. Daylight launch is highly desirable.
- e. A launch azimuth range of 72° to 108° will be targeted.
- f. The launch window is designed for Pacific injection.
- g. Two TLI opportunities are targeted: the first on the second revolution and the second on the third revolution.
- h. TLI will be targeted for a free-return circumlunar trajectory.
 - i. The LOI maneuver will be performed in two stages; the first burn, LOI-1, will result in a 60- by 170-n. mi. elliptical orbit, and the second burn, LOI-2, will circularize the orbit at 60 n. mi. two revolutions later.
 - j. The lunar orbit orientation will be selected so that the spacecraft will pass over a primary G mission site on the thirteenth revolution after LOI-1. This orientation results in a delta time of approximately 24 hours from LOI-1 to DOI.
 - k. Lunar operations will simulate the G mission timeline as closely as possible. The operation will include a G mission type of rendezvous and an APS burn to depletion.
- l. The APS burn to depletion will be targeted to escape the earth-moon system.
- m. The time from LOI-1 to TEI nominally will be approximately 52 hours (26 revolutions), which allows for a rest period after rendezvous. However, an option will exist for performance of TEI on an earlier

revolution if the full rest period is not desired or on a later revolution if observation of an additional G candidate site for the G mission would be possible.

n. The TEI maneuver will be targeted to return as soon as possible to 165° W longitude within the available ΔV capability and without exceeding a return inclination of 40° .

o. The earth relative entry range target will be 1350 n. mi.

5.0 MISSION SUMMARY

In this section, a mission profile is summarized for a May 17, 1969, launch date. The burn times, propellants used, and most mission phase times that are presented in this section are typical of the lunar orbital missions planned for the May and June launch window.

The profile is concisely presented in table 2-I. In this section, major events, spacecraft performance characteristics, and significant trajectory parameters are described in detail for each phase.

In the design of the spacecraft operational mission, the LV mission phases were simulated independently of the exact LV operational trajectory. The trajectory data presented here for the LV mission phases were simulated with LV data received from the MSFC for the Apollo 8 mission. This vehicle configuration is considerably lighter than the actual Mission F configuration. No attempt was made to duplicate exactly the LV operational mission, and the information for the LV phases will differ from that in the official trajectory document (ref. 2). The parameters for the LV mission phases would be considered as typical values only.

5.1 Earth Launch^a

The launch time for this mission was determined to provide an optimized injected payload to support two injection opportunities. The launch time, in particular, differs slightly from the official launch time in the MSFC LV operational trajectory.

^aThe parameters for this phase are presented for information only. The official source for this phase is the MSFC LV operational trajectory (ref. 2).

To provide a daylight launch and acceptable lighting at the target lunar landing site, the mission was designed for a Pacific injection. The launch is summarized as follows.

Date, month, day	May 17, 1969
Time, hr:min:sec, e.s.t.	11:33:49:4
Azimuth, deg	72
Location (Cape Kennedy, Complex 39B)	
Geodetic latitude, deg:min:sec	$28^{\circ}37'38.31''$
Longitude, deg:min:sec	$279^{\circ}22'44.86''$

5.2 Earth Parking Orbit^a

Insertion into EPO occurs at $00^{\text{h}}11^{\text{m}}21.6^{\text{s}}$ g.e.t. The insertion conditions are as follows.

Insertion location

Geodetic latitude, deg	32.7
Longitude, deg	-54.3
Altitude, n. mi.	103.3

Inclination, deg 32.6

The insertion ship positioned at 25° N latitude and 49° W longitude tracks the vehicle for approximately 3 minutes after insertion; minimum elevation angle is 0° . A ground track of the EPO phase is given in figure 5.2-1.

The LV maintains local horizontal attitude throughout the EPO phase except for an inertial hold of approximately 10 seconds immediately after EPO insertion. The total time spent in EPO is $2^{\text{h}}20^{\text{m}}$.

5.3 Translunar Injection

The TLI burn is initiated near the western coast of Australia during the second revolution in EPO. Note that the LV/SC weight model used to simulate the TLI phase was the Apollo 8 configuration and that the burn

^aThe parameters for this phase are approximate and are presented for information only. The official source for this phase is the MSFC launch vehicle operational trajectory (ref. 2).

parameters below do not represent realistic values for the Apollo 10 (Mission F) configuration.

TLI burn initiation

Time, hr:min:sec, g.e.t.	2:31:36.4
Geodetic latitude, deg	-27.8
Longitude, deg	128.6

TLI cutoff

Geodetic latitude, deg	-18.3
Longitude, deg	151.8
Burn duration, sec	307.0
S-IVB propellant used, lb	149 000
Plane change, deg	1.0

The TLI maneuver is initiated in darkness, and the vehicle enters sunlight approximately midway through the TLI burn. (Coverage for the major part of the preignition sequence is provided by Carnarvon, which also provides coverage during the early part of the burn. Additional support of the burn and preignition sequence is supplied by the injection ships (section 2.0). The tracking and lighting and mission events summary is shown in figure 5.3-1.

The TLI burn is biased for a 2 m/sec overburn to compensate for the SPS evasive maneuver that is performed after LM extraction (section 5.5).

5.4 Free-Return Circumlunar Trajectory

Free-return touchdown assumes perfect execution of TLI and no correction maneuvers. It is planned to occur in the Indian Ocean southeast of Madagascar. A more desirable landing position can be insured by application of a corrective maneuver at an acceptable time during either the translunar or transearth coast phases of the circumlunar trajectory. The free-return trajectory is characterized by the following.

Pericynthion

Time, hr:min:sec, g.e.t.	76:11:50.3
Altitude, n. mi.	59.3
Selenographic latitude, deg	1.97
Selenographic longitude, deg	178.5

Return vacuum perigee altitude, n. mi.	15.2
---	------

Transit time from TLI to entry interface, hr:min:sec	147:44:12
---	-----------

Earth entry

Time, hr:min:sec, g.e.t.	150:15:48.2
Altitude, n. mi.	65.8
Geodetic latitude, deg	-18.0
Longitude, deg	45.2
Inclination, deg	33.5

Touchdown

Geodetic latitude, deg	67.1
Longitude, deg	-27.9

5.5 Posttranslunar Injection Events

The summary of the major events from TLI cutoff through S-IVB LOX blowdown is given in table 5.5-I. To determine the separation attitude maneuver (TB-7 plus 900 sec), the sun was constrained to between 32° and 90° of the LV +X-axis. This constraint provides over-the-shoulder lighting and avoids any CSM shadow on the S-IVB for the docking phase. The onboard SC event times will be referenced to TLI ignition (column 1 of table 5.5-I), and the LV event times will be referenced to TB-7. Therefore, the SC event times will vary with respect to TB-7 as the TLI burn time varies. The SC maneuver times referenced to TB-7 in the table assumed a 300-second TLI burn time. The purpose of the evasive maneuver at approximately TB-7 plus 9600 seconds is to decrease the probability of S-IVB recontact and to avoid the ice particles expected to be expelled by the S-IVB during the LOX dump.

The current profile combines an early SPS confidence burn with the evasive maneuver. This SPS burn will have a ΔV of 20 fps and will be approximately 3 seconds in duration. To achieve a burn of this magnitude without jeopardizing the RCS capability to return to a free-return circumlunar mission, the TLI burnout conditions will be biased for a 2-m/sec overspeed at burn termination. The SPS evasive maneuver then will be performed in a direction which will compensate for the TLI bias. The attitude will be pitched down 75° with respect to the local horizontal. This attitude will provide for SC high gain S-band coverage with the steerable antenna, and a roll of approximately ±60° (based on the CSM/S-IVB separation attitude) provides for visual monitoring of the S-IVB during the evasive maneuver burn. At approximately 2 hours after TLI, the S-IVB is ground commanded to assume a local horizontal attitude for the LOX blowdown. The local horizontal attitude components are the following: pitch, 194°; yaw, 0°; roll, 180°. The magnitude of the ΔV that results from the LOX dump is expected to be approximately 120 fps.

The LOX dump maneuver is designed to reduce the probability of SC recontact with the S-IVB and also to prevent S-IVB impact with the earth or moon. Nominally, the LOX dump maneuver results in a

sling-shot trajectory; the S-IVB will pass behind the trailing edge of the moon and will be accelerated by the lunar gravitational field. The result is a heliocentric orbit which avoids either earth or lunar impact.

5.6 Translunar Coast

A ground track of the translunar coast phase is given in figure 5.6-1. Time histories of altitude and true anomaly for the first 10 hours of translunar coast are provided in figures 5.6-2 and 5.6-3, respectively.

Passive thermal control attitude will be maintained throughout most of the translunar coast phase. Four midcourse correction maneuver points have been defined at the following times.

1. TLI plus 7 hours (MCC-1)
2. TLI plus 24 hours (MCC-2)
3. LOI minus 22 hours (MCC-3)
4. LOI minus 5 hours (MCC-4)

The third midcourse correction (MCC-3) will be the prime maneuver to establish the desired lunar approach trajectory. The first two maneuvers will not be performed unless the magnitude of the MCC-3 maneuver exceeds 25 fps. The MCC-1 or MCC-2 maneuver or both will then be performed only if their values exceed the SPS minimum impulse (≈ 3 fps). The MCC-1 and MCC-2 residuals will not be trimmed.

To avoid use of the SPS for the MCC-4 maneuver, the MCC-3 maneuver will be performed if the predicted magnitude of MCC-4 is greater than 3 fps using the SPS. Residuals will be trimmed to within 0.5 fps. If MCC-3 is less than 3 fps and if LOI-1 targeting cannot absorb the uncorrected approach dispersions without a shift greater than 45° in the line of apsides of the 60- by 170-n. mi. orbit, MCC-3 will be performed with the SM RCS; however, if LOI-1 targeting can absorb the dispersions with less than a 45° apsidal shift, MCC-3 will not be performed.

The MCC-4 maneuver will not be performed if the dispersions can be absorbed by the LOI-1 targeting with apsidal rotation less than 45° ; otherwise the maneuver will be performed with the SPS if the ΔV greater than 3 fps or the SM RCS if the ΔV less than 3 fps. The residual will be trimmed to within 1 fps if the SPS is required for the MCC-4 maneuver.

The maneuvers are GNCS controlled and use external ΔV guidance. Unless gimbal lock problems occur, the pad IMU alinement (REFSMMAT) will be used for the MCC-1; the PTC REFSMMAT, for MCC-2 and MCC-3; and

the descent REFSMMAT, for MCC-4. The CSM remains in sunlight during the entire translunar coast phase [table 2-JX(a)]. The duration of the phase is 73 hours 37 minutes. Altitude above the lunar surface for the last 10 hours of translunar coast is provided in figure 5.6-4.

5.7 Lunar Orbit Insertion

The LOI-1 is designed to insert the CSM into approximately a 60- by 170-n. mi. LPO. A time history of trajectory parameters during the burn is presented in figure 5.7-1. The burn was simulated with the external ΔV guidance. A description of the burn is as follows.

LOI initiation

Time, hr:min:sec, g.e.t.	76:08:17.6
Altitude, n. mi.	84.0
Selenographic latitude, deg	0.5
Selenographic longitude, deg	-165.0

Burn duration, min:sec 5:52.5

Inertial burn arc, deg 23.0

Plane change, deg 0.5

ΔV , fps 2867

SPS propellant used, lb 22 971

LOI burnout (start LPO)

Time, hr:min:sec, g.e.t.	76:14:10.1
Altitude, n. mi.	58.9
Selenographic latitude, deg	2.6
Selenographic longitude, deg	172.0
Selenographic inclination, deg	174.3

Period of LPO, hr:min:sec 2:08:36

Altitude of pericynthion of LPO, n. mi. 58.9

Altitude of apocynthion of LPO, n. mi. 168.9

The LOI-1 burn parameters were computed without simulation of the SPS thrust buildup and tailoff. The effect of these, however, is reflected in the burn parameters presented in the simulation data package (ref. 3).

The REFSMMAT used for the LOI-1 burn as well as for all other burns in LPO is the landing site alinement at the nominal G mission landing time relative to DOI.

The target loads for the LOI-1 burn are given in table 5.7-I. More detailed information about the burn, including reset points, navigation updates, and ignition gimbal angles, is given in the F Mission Simulator Data Package (ref. 3).

5.8 Lunar Orbit Circularization

A coplanar circularization burn (LOI-2) is performed to place the CSM in approximately a 60-n. mi. circular LPO after two revolutions in the 60- by 170-n. mi. orbit. The target altitude of the orbit (60 n. mi.) is measured relative to the lunar target site (table 2-IV) and not relative to the mean lunar radius.

The landing REFSMMAT (table 5.8-I) is used, and the CSM is oriented heads down. The burn is initiated near pericynthion of the second revolution. More detailed information is given in reference 4. The characteristics of the burn are the following.

Circularization burn initiation

Time, hr:min:sec, g.e.t.	80:32:12.0
Altitude, n. mi.	58.9
Selenographic latitude, deg	2.8
Selenographic longitude, deg	167.1
Burn duration, sec	14.5
Inertial burn arc, deg	0.7
ΔV, fps	137.5
SPS propellant used, lb	946.2

5.9 CSM/LM Coast From LOI-2 to Undock

At a g.e.t. of $81^{\text{h}}45^{\text{m}}$ or at about 1 minute 13 seconds after LOI-2, the crew begins preparation for IVT to the LM. In the LM, general housekeeping and equipment storage is performed. Also, short checkout will be performed on the LM VHF and OPS systems. After about 2 hours 40 minutes in the LM, the CDR and LMP perform IVT to the CSM and close the hatch. At a g.e.t. of approximately $84^{\text{h}}40^{\text{m}}$, landmark tracking is performed on a pseudosite with a sun elevation angle of approximately 3° . An inertial hold is initiated at a g.e.t. of $86^{\text{h}}00^{\text{m}}$ for an 8-hour crew rest period.

The rest period is ended at a g.e.t. of $94^{\text{h}}00^{\text{m}}$. After a 1-hour eat period, the CDR and IMP perform IVT to enter the LM and begin LM checkout. At a g.e.t. of $96^{\text{h}}50^{\text{m}}$ (revolution 11), landmark tracking is performed on the target site. The LM checkout is completed, and undocking occurs at $98^{\text{h}}30^{\text{m}}$ during revolution 12 or approximately 4 hours 30 minutes after wakeup. The lunar ground tracks for the total lunar orbital phase is shown in figure 5.9-1. The CSM tracking, lighting, and events summary for the total lunar orbital phase is shown in figure 5.9-2.

5.10 LM Undock and CSM Separation

Undocking will occur 30 minutes prior to the RCS separation burn. After the CSM undocks from the LM, the CSM will perform stationkeeping at a distance of 30 feet from the LM for LM inspection. After completion of the inspection, the LM will perform stationkeeping while the CMP prepares for the RCS separation. At approximately a 180° central angle prior to DOI, the CSM performs a 2.5 fps radially downward separation maneuver, which places the LM and CSM in equiperiod orbits. Rendezvous will be accomplished from the equiperiod orbits if the DOI maneuver is not performed.

5.11 Rendezvous Sequence

5.11.1 Sequence summary.- The basic objective of the rendezvous sequence on the Apollo Mission F is to simulate as nearly as possible the LLM rendezvous profile after LM insertion following ascent from the lunar surface. The rendezvous sequence is shown in table 5.11-I. After separation of the LM and CSM, the rendezvous activities are initiated by the CSM separation maneuver (minifootball, section 5.10) at $98^{\text{h}}55^{\text{m}}40^{\text{s}}$ g.e.t. Then the LM must perform a DOI maneuver and a phasing maneuver to establish the proper relative conditions (LM 49.4 n. mi. below and 270.0 n. mi. behind the CSM) at the simulated insertion point over the target site (34° E). After the insertion maneuver has been completed, the LM will compute and execute the coelliptic sequence that is planned for the LLM rendezvous. The sequence of CSI, CHD, and TPI will result in LM approach, braking, and docking at approximately $106^{\text{h}}32^{\text{m}}00^{\text{s}}$ g.e.t., which completes the 7.5-hour exercise that began with separation. A detailed discussion of the rendezvous activities is given in sections 5.11.2 through 5.11.9.

The orbital schematic for the nominal F mission rendezvous is presented in figure 5.11-1. The relative motion of the descent stage with respect to the ascent stage after the staging sequence is presented in figure 5.11-4. A tracking, lighting, and mission events summary for the rendezvous sequence is presented in figure 5.11-5.

5.11.2 DOI.- After the CSM separation maneuver at $98^{\text{h}}55^{\text{m}}40^{\text{s}}$ g.e.t., the LM will fine align the platform and will align the AGS to the PGNCS in preparation for the DOI maneuver. The DOI maneuver is ground computed to be executed 195° prior to the target site, which duplicates the same maneuver required in the LLM. The DOI maneuver is external ΔV maneuver performed with the DPS in a horizontal retrograde direction so that the resultant LM pericynthion is 50 000 feet (referenced to the landing site radius) and is 15° up range from the landing site. The 72.8 fps maneuver is performed at $99^{\text{h}}54^{\text{m}}12^{\text{s}}$ g.e.t. with 10-percent thrust for 15 seconds and 40-percent thrust for 12.7 seconds. The target loads for the DOI maneuver are shown in table 5.11-II.

5.11.3 Phasing.- After the DOI maneuver, the LM will prepare for a landing radar test to be conducted as the vehicle passes over the target site at 34° E longitude and at an altitude of approximately 50 000 feet. Because the LM will lead the CSM (fig. 5.11-4) during this first pass over the site, a phasing maneuver is performed approximately 10 minutes after the site is passed to place the LM in a dwell orbit so that eventually the LM will fall behind the CSM and will trail the CSM by approximately 270 n. mi. at the time of the second pass, at which time the lunar landing mission relative profile can be simulated. The phasing maneuver is a ground-computed maneuver with an external ΔV of 193.5 fps initiated with the DPS at $101^{\text{h}}06^{\text{m}}35^{\text{s}}$ g.e.t. By use of the two-impulse processor, the maneuver is targeted to establish the nominal LLM phase and height offset relative to the CSM at the time of insertion. The target loads for the phasing maneuver are shown in table 5.11-II. The posigrade burn at a 26.1° pitch above the local horizontal will place the LM in a 194.4- by 9.8-n. mi. orbit. The DPS burn will be started at 10-percent thrust for 26 seconds and will be increased to full throttle (92.5 percent) for 16 seconds.

5.11.4 Insertion.- During the LM phasing orbit, the LM and CSM will conduct onboard tracking to determine the orbits. The onboard tracking data may be used by the ground to update the required insertion maneuver. The insertion maneuver will initiate the sequence that is designed to simulate the in-orbit ascent rendezvous of the LM after the lunar liftoff on the LLM. Prior to insertion, the LM will stage the DPS so that the burn may be executed with the APS. Current plans call

for the staging to occur at $102^{\text{h}}53^{\text{m}}26^{\text{s}}$ g.e.t., approximately 10 minutes prior to insertion. While in a retrograde attitude, the LM will thrust posigrade 2 fps with the -X RCS jets, will stage, and immediately will null this ΔV with 2 fps retrograde with the +X jets. The result of the separation maneuver is to send the descent stage ahead of and above the ascent stage so that no recontact can occur after the ascent stage performs insertion. The relative motion of the descent stage with respect to the LM can be seen in figure 5.11-2. At $103^{\text{h}}03^{\text{m}}29^{\text{s}}$ g.e.t.,

the APS thrusts at a 152.6° pitch for 15 seconds to impart a retrograde ΔV of 213 fps and to place the LM into a 43.6- by 9.8-n. mi. orbit. Apocynthion occurs 51 minutes later. The 43.6- by 9.8-n. mi. orbit is identical to the orbit planned after IM insertion in the LLM, and the insertion maneuver is scheduled 5 minutes prior to entry into darkness to duplicate the LLM lighting conditions. The insertion maneuver is also targeted by the ground two-impulse processor which establishes the nominal CSI offset (LM 14.7 n. mi. below and 148 n. mi. behind the CSM) at the nominal time. Target loads for the insertion maneuver are shown in table 5.11-IV.

5.11.5 CSI.- After insertion, the LM will realine its platform and will begin radar tracking of the CSM to determine the orbits of the vehicles for onboard computation of the coelliptic sequence. The CSI maneuver will be scheduled for the apocynthion at $103^{\text{h}}54^{\text{m}}40^{\text{s}}$ g.e.t. and will be calculated to cause TPI to occur at the midpoint of darkness approximately 94 minutes later. The nominal relative condition will be such that the CSI will place the LM in a 46.2- by 42.9-n. mi. orbit, 15.0 n. mi. below the CSM orbit at the time of CDH, one-half an orbital period after the CSI. The CSI will be performed with the four +X RCS jets so that the interconnect can be opened and APS propellant can be used. The 32.1-second burn is horizontal and adds a posigrade ΔV of 50.5 fps. The target loads are shown in table 5.11-V.

5.11.6 Plane change technique.- An out-of-plane component, which nominally is not required, will be applied in conjunction with the CSI if an out-of-plane velocity is detected prior to the CSI. The out-of-plane component will be targeted to null to zero the out-of-plane velocity, which will force the existence of a common node approximately 90° later where the separate PC maneuver is scheduled. At PC, the out-of-plane velocity is again nulled to zero and a coplanar situation is established. If the out-of-plane situation is not determined soon enough to begin the PC at the CSI, the nodal shift would be initiated at the time of PC and completed in conjunction with the CDH. However, the CSI-PC sequence is more economical than the PC-CDH sequence because the in-plane component at the CSI is considerably larger than the in-plane component at CDH.

5.11.7 CDH.- After the CSI, the LM will continue to track the CSM and will compute the required CDH maneuver to be done at $104^{\text{h}}52^{\text{m}}41^{\text{s}}$ g.e.t. Normally, the CDH will be a small radial burn designed to coellipticize the LM orbit with the orbit of the CSM. If the CSM orbit were perfectly circular, the CDH would be zero; however, because of the simulated 61- by 58-n. mi. CSM orbit, a downward ΔV of 5.8 fps is required. The two-jet +Z thrusters were used in this simulation; however, the -X jets could be used so that radar lock-on at an elevation angle of approximately 9.5° above the local horizontal would not be disturbed. The

7.3-second burn places the LM in a 46.2- by 42.9-n. mi. orbit, 15 n. mi. below the CSM orbit and coelliptic with it. The target loads for the CDH maneuver are presented in table 5.11-VI.

5.11.8 TPI.- Radar tracking continues after CDH so that the LM may compute the required burn (TPI) when the elevation angle to the CSM reaches 26.6° above the LM local horizontal. Nominally, the maneuver should occur approximately 36.5 minutes after CDH, when the LM is 23 minutes into darkness. TPI will be calculated to start the LM on an intercepting orbit; theoretically, rendezvous would occur after 130° of CSM central angle travel. The 25.3-fps burn is planned to be executed with the four +X jets to use the APS propellant through the interconnect. However, this arrangement may cause a temporary loss of radar lock, which is not considered to be a problem. The TPI ignition is at $105^{\text{h}}28^{\text{m}}59^{\text{s}}$ g.e.t., and the burn duration is approximately 16 seconds. The target loads for the TPI maneuver are presented in table 5.11-VII.

5.11.9 Rendezvous midcourse corrections and braking.- The LM will track the CSM after TPI and will perform nominally zero midcourse correction maneuvers 15 minutes later and 30 minutes later. The braking schedule assumed for this trajectory simulation calls for a reduction in range rate to 15 fps at the 1-n. mi. gate, to 5 fps at 1000 feet, and to 0.25 fps at 300 feet. The braking schedule may be changed slightly after further simulations; line-of-sight corrections will be made as required. Final approach and stationkeeping should occur at approximately $106^{\text{h}}17^{\text{m}}00^{\text{s}}$ g.e.t., approximately 25 minutes after the vehicles enter sunlight on the backside of the moon. Docking should begin at approximately $106^{\text{h}}32^{\text{m}}00^{\text{s}}$ g.e.t. to complete 7.5 hours of rendezvous activities.

5.12 APS Burn to Depletion

At approximately $107^{\text{h}}15^{\text{m}}00^{\text{s}}$ g.e.t., just prior to earth LOS, the CSM/LM establishes an inertial attitude which is suitable for LM steerable antenna communications during and after the APS burn to depletion. The antenna is in a locked position. Near 90° E longitude, the unmanned LM is jettisoned in attitude hold, and the CSM performs a radially upward separation maneuver of approximately 2 fps, which will place the CSM above and behind the LM at the time of the APS burn.

The ullage maneuver and the APS burn are initiated under PGNCS control, and after confirmation of burn initiation a command is sent to transfer control to the AGS. The ascent stage will have been in attitude hold since jettison. Whether either or both of the RCS interconnects

will be open will depend on the RCS usage up to that time in the mission and will probably be a real-time decision. The need for attitude hold to be maintained during the burn and as long thereafter as possible could be satisfied either with one interconnect open or with both closed. However, if the RCS margin is low enough at the time of jettison, both interconnects would be open to assure attitude control during the entire burn. In this case, ascent stage tracking after the burn would not be assured. The characteristics of the burn are as follows.

Burn initiation

Time, hr:min:sec, g.e.t.	109:03:41.4
Δt from LM jettison, min	30
Selenographic latitude, deg	-.22
Selenographic longitude, deg	0.0
Estimated propellant	
available, lb	2373
Vehicle attitude, local horizontal	
Pitch, deg	0
Yaw, deg	0
Roll, deg	0

Burn termination

Burn duration, min:sec	3:2.5
Burnout velocity, fps	8960
ΔV attained, fps	3616
Selenographic latitude, deg	-1.6
Selenographic longitude, deg	-13.8
Burn arc, deg	13.8
Selenographic longitude of the lunar sphere exit, deg W	≈134

The resultant ascent stage trajectory is hyperbolic with respect to the earth-moon system, which assures a heliocentric orbit.

5.13 CSM Coast from APS Burn to Depletion to TEI

Shortly after the APS burn to depletion at a g.e.t. of $110^{\text{h}}00^{\text{m}}00^{\text{s}}$, an inertial attitude hold is initiated for an 8-hour crew rest period. After the rest period, four consecutive revolutions of landmark tracking will be performed, which will involve tracking either three or four landmarks per sunlight pass. After these four revolutions of tracking have been performed, one revolution of terminator-to-terminator stereo strip photography will be performed.^a

^aThe terminator-to-terminator stereo photography will require adding one revolution to the lunar orbit timeline which is not included in this document.

5.14 Transearth Injection

The TEI maneuver occurs $51^{\text{h}} 37^{\text{m}} 00^{\text{s}}$ after LOI-1. A time history of significant parameters during the burn is provided in figure 5.14-1. The burn was targeted for a 63-hour transearth flight time. The target loads and REFSMMAT for the burn are presented in table 5.14-I. The characteristics of the burn are presented below.

Initiation time, hr:min:sec, g.e.t	127:51:34.8
Selenographic latitude, deg	0.5
Selenographic longitude, deg	168.0
Burn duration, sec	159.6
ΔV , fps	3250.9
SPS propellant used, lb	10 400
Plane change	1.75
Burnout	
Flight-path angle, deg	3.0
Altitude, n. mi.	60.4
Selenographic latitude, deg	1.3
Selenographic longitude, deg	157.6
Entry velocity (inertial), fps	36 210.5

5.15 Transearth Coast

A groundtrack of the transearth coast phase is provided in figure 5.15-1. Altitude above the moon is shown for the first 10 hours of coast in figure 5.15-2. Three midcourse decision points have been defined for the transearth phase.

1. MCC-5, TEI plus 15 hours
2. MCC-6, EI minus 15 hours
3. MCC-7, EI minus 3 hours

The maneuvers will be targeted for corridor control only. The midcourse strategy, which includes the threshold values for each maneuver, is contained in reference 5. Altitude is plotted against time for the last 10 hours of transearth coast in figure 5.15-3. The CSM remains in sunlight from TEI until darkness, which occurs approximately 21 minutes prior to EI. The last ground station coverage is by Honeysuckle [table 2-VIII(c)], which terminates at 0° elevation approximately 3 minutes prior to EI.

5.16 Entry

The entry phase of the operational trajectory was simulated with the Apollo Reentry Simulation program with six-degrees-of-freedom. Three-degree-of-freedom trajectories were used to determine the CM maneuver footprint. The entry corridor is presented in figure 5.16-1.

At the nominal EI, $191^{\text{h}}18^{\text{m}}16^{\text{s}}$ after lift-off, the CM is at an altitude of 399 720 feet, and the coordinates are 18.315° S geodetic latitude and 171.29° E longitude. Inertial velocity, flight-path angle, and azimuth at this point are 36 210 fps, 6.49° below the local horizontal, and 98.56° , respectively.

A plot of the CM maneuver footprint and the nominal ground trace on a map of the entry area are presented in figure 5.16-2. The footprint is extended to a 3500-n. mi. entry range. The nominal touchdown target location is 1350 n. mi. down range from the entry interface position, and the coordinates of the target are 165° W longitude and 20.25° S geodetic latitude. A sequence of pertinent events is given in table 5.16-I and includes the periods of communication blackout which occur along the trajectory. The guidance phases are shown in figure 5.16-3, which shows altitude as a function of range to the target. Time histories of the bank angle commanded by the guidance system, by the load factor, and by altitude are presented in figure 5.16-4. The load factor at the c.g. reaches a first maximum of 6.35g and a second maximum of 5.99g. Time histories of the total heating rate and the total heat load are presented in figure 5.16-5. The maximum total heating rate is 277.8 Btu/ft²/sec, and the total heat load is 24 355 Btu/ft². Time histories for inertial and relative velocity and flight-path angles are presented in figure 5.16-6.

The CM RCS uses 11.55 pounds of propellant for the separation and attitude hold maneuvers before the spacecraft reaches 400 000 feet. The RCS uses 19.24 pounds of propellant to perform the guidance commands during the remainder of the entry. A time history of the total RCS propellant consumed from separation is presented in figure 5.16-7. In figure 5.16-8, the altitude is plotted in relation to relative velocity, and the boundaries for S-band and C-band communication blackout are shown (ref. 6). Time histories for the primary DSKY displays, commanded bank angle, inertial velocity, and altitude rate are shown in figure 5.16-9. Time histories for the final phase DSKY displays, commanded bank angle, cross-range error, and down-range error are shown in figure 5.16-10.

The drogue parachute deployment sequence begins at an altitude of 23 300 feet, 8 minutes 32 seconds after EI. The two drogue parachutes

are deployed 2 seconds later. At an altitude of 10 500 feet, the low altitude baroswitch closes, and the drogue parachutes are disconnected. The three main parachutes are deployed 1 second after the baroswitch closes. The CM, suspended on the main parachutes, reaches splashdown 14 minutes 20 seconds after EI. The relative velocity and relative flight-path angle are plotted against time from drogue chute deployment in figure 5.16-11. Load factor and altitude are plotted against time from drogue chute deployment in figure 5.16-12.

An EMS scroll (NON-EXIT pattern) is presented in figure 5.16-13(a) with the reference trajectory from 0.05g superimposed upon it. This pattern has limit lines which allow the crew to monitor the entry trajectory to prevent an exit by the spacecraft from the atmosphere ($g < 0.2$). The commanded bank angle and EMS range-to-go are plotted against the inertial velocity in figure 5.16-13(b).

The following input was used in the generation of the operational entry trajectory.

5	1.772	-41.939	-1.539

^aAssumed mean lunar radius of 938.5 n. mi.

TABLE 2.0-V.- SPACECRAFT WEIGHT SUMMARY

Total CSM dry, lb	23 098
CSM inert, lb	12 300
SM inert, lb	10 700
SLA ring, lb	98
Total SPS propellant tanked, lb	40 634
SPS propellant usable, lb	40 264
SPS propellant unusable, lb	370
Total LM loaded, lb	30 849
LM descent stage inert, lb	4 703
LM DPS propellant tanked, lb.	18 134
LM ascent stage inert, lb	5 393
LM APS propellant tanked, lb	2 619
SLA, lb	4 000
Total injected Saturn payload, lb	98 581

TABLE 2.0-VI.- ENGINE PERFORMANCE SUMMARY

Propulsion system	I_{sp} , sec	Thrust per engine, lb	Flow rate per engine, lb/sec
(a) Service module			
SPS	314.6	20 500	65.16
SM RCS	277.3	102.8	0.371
(b) Lunar module			
DPS (full throttle)	302.1 (average)	9712.5	32.15
APS	306.3	3500.0	11.43
LM RCS	273.0	100.0	0.37

TABLE 2.0-VII.- ASSUMED MISSION-INDEPENDENT EXPENDABLES^a

Mission-independent SPS budget

Translunar MCC, fps	120
Transearch MCC, fps	00
Total	120

SPS propellant allowances

Unbalance meter, lb	100
Mean outage, lb	52
Dispersions, lb	548
Total	700

Other expendables

Translunar coast, lb	332
Lunar orbital coast, lb	298
Transearch coast, lb	290
Total	920

^aThese figures were used only as estimates to compute the end of mission propellant reserves. A detailed dispersion and consumables analysis will be performed and will be published later.

^aThe enclosed radar table gives data for the coast phases only. If a station does not acquire or terminate at the nominal minimum elevation of 0° or 5°, the user must then investigate to see if the event took place because of exceeding maximum range, occultation, or end of a phase. All numbers are rounded off to the nearest unit of time, degrees, or nautical miles.

^bTime is g.s.t. and range is slant range from the station to the spacecraft (n. mi.). See figure A-3b in the appendix for definitions of RA and DEC, figure A-3a for AZ and ELV, and figures A-3c and A-3d for X and Y. RA is equivalent to -HA in figure A-3b.

TABLE 5.5-I.- SUMMARY OF EVENTS FROM TLI CUTOFF THROUGH LOX DUMP

Time from TLI ignition ^a	Time from TB-7 sec ^b	Event	ΔV , fps	Comments
	0	Hold cutoff attitude		
	20	Command and hold local horizontal		
	900	Initiate maneuver to separation attitude		
	1200	Freeze separation attitude inertially		Latest time for maneuver to be completed
1800	1500	Begin SC separation/SLA jettison	0.8	
1835	1535	Null 0.3 fps separation rate	.3	-X RCS
1840	1540	Pitch 180° (SC)		1.5/deg/sec
1960	1660	Null pitch Start roll 60°		.5 deg/sec
2080	1780	Null 0.5 fps separation rate and initiate 1 fps closing rate	1.5	+X RCS
2230	1930	Null 1 fps closing rate	1	-X RCS
2235	1935	Begin dock		Estimated worst case dock completed by TLI plus 1.5 hr
5700	5400	LM/CSM undock from S-IVB	1.6	Spring ejection and 5 sec -X RCS
5800	5500	Maneuver to evasive maneuver attitude		Pitch down 75° with respect to local horizontal 0.5 deg/sec rates
6300	6600	Begin SPS evasive maneuver	20	SPS between 1:35 and 1:50 after TLI
7500	7200	Receive ground command to start TB-8		Earliest possible time to initiate TB-8
7505	7205	Start maneuver to LOX dump attitude		Local horizontal attitude pitch = 194° yaw = 0° roll = 180°
8220	7920	Initiate LOI dump	120	

^aThe SC maneuver times will be referenced to TLI ignition, the LV maneuvers to TB-7.^bThe times of the SC maneuvers referenced to TB-7 (column 2) are approximate and based on a 300-second TLI burn time. These times will change as TLI burn time changes.
